Simple R Functions

January 26, 2018

1.

(a) Write functions tmpFn1 and tmpFn2 such that if xVec is the vector $(x_1, x_2, ..., x_n)$, then tmpFn1(xVec) returns vector $(x_1, x_2^2, ..., x_n^n)$ and tmpFn2(xVec) returns the vector $(x_1, \frac{x_2^2}{2}, ..., \frac{x_n^n}{n})$.

Here is tmpFn1

```
tmpFn1 <- function(xVec){
   return(xVec^(1:length(xVec)))
}

## simple example
a <- c(2, 5, 3, 8, 2, 4)

b <- tmpFn1(a)
b</pre>
```

[1] 2 25 27 4096 32 4096

and now ${\tt tmpFn2}$

```
tmpFn2 <- function(xVec2){
    n = length(xVec2)
    return(xVec2^(1:n)/(1:n))
}

c <- tmpFn2(a)
c</pre>
```

[1] 2.0000 12.5000 9.0000 1024.0000 6.4000 682.6667

(b) Now write a fuction tmpFn3 which takes 2 arguments x and n where x is a single number and n is a strictly positive integer. The function should return the value of

$$1 + \frac{x}{1} + \frac{x^2}{2} + \frac{x^3}{3} + \ldots + \frac{x^n}{n}$$

```
tmpFn3 <- function(x, n){
   1 + sum((x^(1:n))/ (1:n))
}

c <- tmpFn3(1, 7)
c</pre>
```

[1] 3.592857

2. Write a function tmpFn(xVec) such that if xVec is the vector $x = (x_1, ..., x_n)$ then tmpFn(xVec) returns the vector of moving averages:

$$\frac{x_1 + x_2 + x_3}{3}, \frac{x_2 + x_3 + x_4}{3}, ..., \frac{x_{n-2} + x_{n-1} + x_n}{3}$$

Try out your function. tmpFn(c(1:5,6:1))

```
tmpFn <- function(xvec){
  x <- length(xvec)
  (xvec[1:(x-2)] + xvec[2:(x-1)] + xvec[3:x]) / 3
}
tmpFn(c(1:5, 6:1))</pre>
```

```
## [1] 2.000000 3.000000 4.000000 5.000000 5.333333 5.000000 4.000000 3.000000 ## [9] 2.000000
```

3. Consider the continuous function

$$f(x) = \begin{cases} x^2 + 2x + 3 & if & x < 0\\ x + 3 & if & 0 \le x < 2\\ x^2 + 4x - 7 & if & 2 \le x \end{cases}$$

Write a function tmpFn which takes a single argument xVec. the function should return the vector the values of the function f(x) evaluated at the values in xVec. Hence plot the function f(x) for -3 < x < 3.

```
tmpFn <- function(x){
   ifelse(x < 0, x^2 + 2*x + 3, ifelse(x>= 0 & x< 2, x+3, x^2 + 4*x - 7))
}

xVec <- seq(-3, 3, len = 10)
xVec

## [1] -3.0000000 -2.3333333 -1.6666667 -1.0000000 -0.3333333 0.3333333
## [7] 1.0000000 1.66666667 2.3333333 3.0000000

tmpFn(xVec)

## [1] 6.000000 3.777778 2.444444 2.000000 2.444444 3.333333 4.000000</pre>
```

```
## [8] 4.666667 7.777778 14.000000
```

4. Write a function which takes a single argument which is a matrix. The function should return a matrix which is the same as the function argument but every odd number is doubled.

Hence the result of using the function on the matrix

$$\begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix}$$

should be:

$$\begin{bmatrix} 2 & 2 & 6 \\ 10 & 2 & 6 \\ -2 & -2 & -6 \end{bmatrix}$$

```
matFn <- function(mat)</pre>
{
  mat[mat\%2 == 1] <- 2 * mat[mat\%2 == 1]
  \mathtt{mat}
}
matFn(matrix(c(1,1,3,5,2,6,-2,-1,-3), nrow = 3, byrow = TRUE))
         [,1] [,2] [,3]
##
## [1,]
            2
                  2
                  2
## [2,]
           10
                       6
           -2
                 -2
## [3,]
                      -6
```

5. Write a function which takes 2 arguements n and k which are positive integers. It should return the nxn matrix:

$$\begin{bmatrix} k & 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & k & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & k & 1 & \cdots & 0 & 0 \\ 0 & 0 & 1 & k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & k & 1 \\ 0 & 0 & 0 & 0 & \cdots & 1 & k \\ \end{bmatrix}$$

```
matFn2 <- function(n, k){
  mat <- diag(k, nrow = n)
  mat[abs(row(mat) - col(mat)) ==1] <- 1
  mat
}
matFn2(5, 2)</pre>
```

```
[,1] [,2] [,3] [,4] [,5]
## [1,]
            2
                            0
                 1
                       0
## [2,]
            1
                 2
                       1
                            0
                                  0
## [3,]
                       2
                            1
            0
## [4,]
            0
                 0
                            2
                       1
                                  1
## [5,]
                                  2
            0
                 0
                       0
                             1
```

6. Suppose an angle α is given as a positive real number of degrees.

```
If 0 \le \alpha < 90 then it is quadrant 1. If 90 \le \alpha < 180 then it is quadrant 2. if 180 \le \alpha < 270 then it is quadrant3. if 270 \le \alpha < 360 then it is quadrant 4. if 360 \le \alpha < 450 then it is quadrant 1. And so on . . .
```

Write a function quadrant (alpha) which returns the quadrant of the angle α .

```
quadrant <- function(alpha){
    alpha <- alpha %% 360
    ifelse(alpha < 360, ifelse(alpha <270, ifelse(alpha < 180, ifelse(alpha < 90, 1, 2), 3), 4))
}
quadrant(100)
## [1] 2
quadrant(250)
## [1] 3
quadrant(5)
## [1] 1
quadrant(300)
## [1] 4
quadrant(400)
## [1] 1</pre>
```

(a) Zeller's congruence is the formula:

$$f = ([2.6m - 0.2] + k + y + [y/4] + [c/4] - 2c)mod7$$

where [x] denotes the integer part of x; for example [7.5] = 7.

Zeller's congruence returns the day of the week f given:

```
k = the day of the month
```

y =the year in the century

c =the first 2 digits of the year (the century number)

m = the month number (where January is month 11 of the preceding year, February is month 12 of the preceding year, March is month 1, etc.)

For example, the date 21/07/1, 963 has m = 5, k = 21, c = 19, y = 63;

the date 21/2/63 has m = 12, k = 21, c = 19, and y = 62.

Write a function weekday(day,month, year) which returns the day of the week when given the numerical inputs of the day, month and year.

Note that the value of 1 for f denotes Sunday, 2 denotes Monday, etc.

```
weekday <- function(day, month, year) {
    m <- month - 2
    if(m <= 0) {
        m <- m + 12
        year <- year - 1
    }
    k <- day
    cent <- year %/% 100
    y <- year %/% 100
    wday <- floor(2.6*m - 0.2) + k + y + y %/% 4 + cent %/% 4 - 2 * cent</pre>
```

```
c("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday", "Saturday") [1+wday%%7]
}
```

(b) Does your function work if the input parameters day, month, and year are vectors with the same length and valid entries?

This function does not work on vectors because of the if statement.
